

Composition/ Action

It has high enzymatic activity and acts as a diffuser of other ingredients.

It works directly on eliminating water retention and reducing fat.

- Collagenase - functions in the metabolism of collagen. This enzyme dissolves lumps of accumulated cellulite. Helps break down fibrous tissue by dissolving collagen. The elimination of these solidified collagen fibers and the breakdown of fat cells help loosen the outer tissue, making the skin smoother.
- Hyaluronidase - breaks down polysaccharides that are responsible for the accumulation of fluids. It is an enzyme that causes the reversible depolymerization of existing hyaluronic acid around connective tissue cells, thereby reducing the viscosity of this tissue and making it more permeable to liquid diffusion.
- Lipase - functions in the metabolism of triglycerides. It is an enzyme whose role is to break fat molecules into smaller ones, making them easier to absorb by the body and therefore released faster. This way you can lose weight and reduce volume.
